

# The LEAPS Report The Household Perspective

Jishnu Das

(World Bank and Centre for Policy  
Research, New Delhi)

## The View from Above: Common Beliefs about Education

- Households do not “care” about education for their children.
  - They do not value education
  - They make small investments
  - They keep children out of school so that they can work
  - Investments in female education are much lower
- Therefore, households must be “cajoled” and “incentivized” to send their children to schools

# The view from below: The data speaks

- Five facts about what households know and what households do from the LEAPS surveys

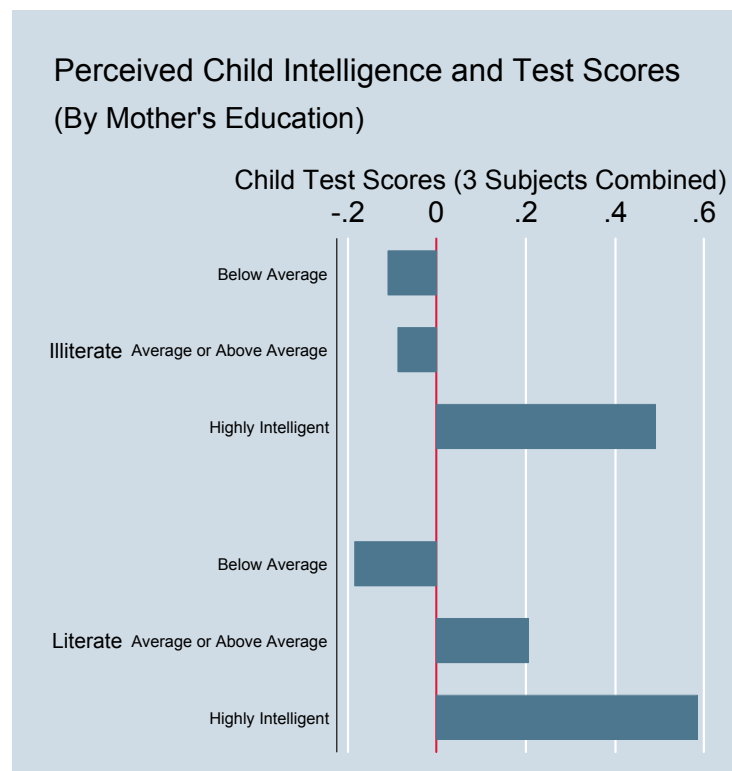

# Fact 1: Parents are investing heavily in their children's education

- Households are spending on their children's education
  - Among the richest third rural households, spending is greater than that of the government
  - Even among the poorest third, households are spending substantially on children's education

## Fact 2: Parents are reasonably well informed

- We asked parents to tell us which children they thought were “more” intelligent
- Children ranked as more intelligent by parents reported far higher test-scores
- Results are identical for literate and illiterate mothers (and fathers)

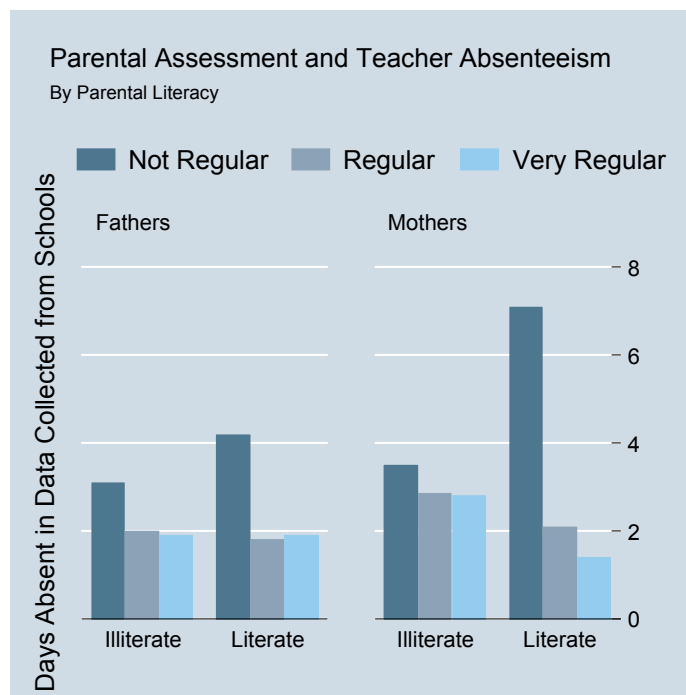

# Fact 2: Parents are reasonably well informed

- We asked parents to tell us which schools they thought were better
- Schools ranked as better by parents reported far higher test-scores
- Results are identical for literate and illiterate mothers (and fathers)

## Fact 2: Parents are reasonably well informed

- We asked parents to tell us which teachers they thought were regular
- Teachers assessed as regular by parents had lower reported absenteeism
- Results are similar for literate and illiterate fathers
  - Literate mothers are the most accurate

## Fact 3: Yet parents discriminate

- Two main types of discrimination
  - Girls are far less likely to travel “farther” to school
  - Educational investments on children perceived as “less intelligent” by parents are much lower

# The distance penalty

- Most children live within 300 meters of a school
- Yet, the size of the distance penalty is large for girls
- Enrollment drops by *20% points* every 500m a school is farther from home

# The distance penalty: mitigating factors

- Nothing decreases the distance penalty for girls
  - Except for mother's education

# The distance penalty: mitigating factors

Table 4.1: Household and Child Characteristics, Enrollment, and the Distance Gradient

|   | Boys                     |                                  | Girls                    |                                  |
|---|--------------------------|----------------------------------|--------------------------|----------------------------------|
|   | Likelihood of Enrollment | Effect of Distance on Enrollment | Likelihood of Enrollment | Effect of Distance on Enrollment |
| <b>Child Intelligence</b>                 | Increases                | Reduces the distance penalty     | Increases                | No Change                        |
| <b>Child in teenage years</b>             | Decreases                | No Change                        | Decreases                | No Change                        |
| <b>Household Wealth</b>                   | Increases                | No Change                        | Increases                | No Change                        |
| <b>Educated Adult Female in Household</b> | Increases                | No Change                        | Increases                | Reduces the distance penalty     |

- We do not understand what drives the distance-penalty, but this is a first order issue
  - It accounts for 60% of the enrollment difference between boys and girls

## Do parents discriminate?

- Much has been said about gender discrimination.
- What about *other forms* of discrimination?
- How do parents allocate educational investments across children?

# Choosing winners

- Parents rank children very easily
- And are investing a lot more in children they think are “more intelligent”
- Parents “pick” winners and invest in them

# Parental Heterogeneity

|                               | Goes to Closest Eligible |               |                | Bypasses          |                    |                    |                     | Total |
|-------------------------------|--------------------------|---------------|----------------|-------------------|--------------------|--------------------|---------------------|-------|
|                               | Not Enrolled             | Public School | Private School | Public for public | Private for Public | Public for Private | Private for Private |       |
| <b>Number of Observations</b> | 1,369                    | 827           | 414            | 668               | 1,443              | 386                | 421                 | 5,528 |
| <b>% of all children</b>      | 24.76                    | 14.96         | 7.49           | 12.08             | 26.1               | 6.98               | 7.62                | 100   |

- Given the distance penalty, one automatic conclusion is that
  - Children go to the closest school
- But that is incorrect
  - Some parents care about distance, others about quality and others about cost
- Any policy effect depends on what proportion of each type of household are in the village

## Adding it up

- Two things that are clear
  - Figuring out how to get children from “farther” away, especially girls, to school is critical
  - Education for all has to mean a focus on children who are not receiving adequate investments at home
    - Which is largely about improving the quality of government schools

## Adding it up

- What is not clear
  - Given large parental investments, any policy effect will depend on how parents respond.
  - We *cannot* predict this from the data since different parents are different
- Programs have to be evaluated on a pilot basis with careful data on household responses
